

# **Software Project Management** (UNIT 3)

# Organization of this Lecture:

- ⌘ Introduction to Project Planning
- ⌘ Software Cost Estimation
  - ☒ Cost Estimation Models
  - ☒ Software Size Metrics
  - ☒ Empirical Estimation
  - ☒ Heuristic Estimation
  - ☒ COCOMO
- ⌘ Staffing Level Estimation
- ⌘ Effect of Schedule Compression on Cost
- ⌘ Summary

# Introduction

⌘ Many software projects fail:

⏏ due to faulty project management practices:

⊗ It is important to learn different aspects of software project management.

# Introduction

⌘ Goal of software project management:

☑ enable a group of engineers to work efficiently towards successful completion of a software project.

# Responsibility of project managers

- ⌘ Project proposal writing,
- ⌘ Project cost estimation,
- ⌘ Scheduling,
- ⌘ Project staffing,
- ⌘ Project monitoring and control,
- ⌘ Software configuration management,
- ⌘ Risk management,
- ⌘ Managerial report writing and presentations, etc.

# Introduction

⌘ A project manager's activities are varied.

☑ can be broadly classified into:

☒ project planning,

☒ project monitoring and control activities.

# Project Planning

- ⌘ Once a project is found to be feasible,
  - ☑ project managers undertake project planning.

# Project Planning Activities

## ⌘ Estimation:

- ⌘ Effort, cost, resource, and project duration

## ⌘ Project scheduling:

## ⌘ Staff organization:

- ⌘ staffing plans

## ⌘ Risk handling:

- ⌘ identification, analysis, and abatement procedures

## ⌘ Miscellaneous plans:

- ⌘ quality assurance plan, configuration management plan, etc.

# Project planning

⌘ Requires utmost care and attention --- commitments to unrealistic time and resource estimates result in:

- ⊡ irritating delays.
- ⊡ customer dissatisfaction
- ⊡ adverse affect on team morale
  - ⊗ poor quality work
- ⊡ project failure.

# Sliding Window Planning

⌘ Involves project planning over several stages:

- ☑ protects managers from making big commitments too early.

- ☑ More information becomes available as project progresses.

- ☑ Facilitates accurate planning

# SPMP Document

⌘ After planning is complete:

- ☑ Document the plans:

- ☑ in a Software Project Management Plan(SPMP) document.

# Organization of SPMP Document

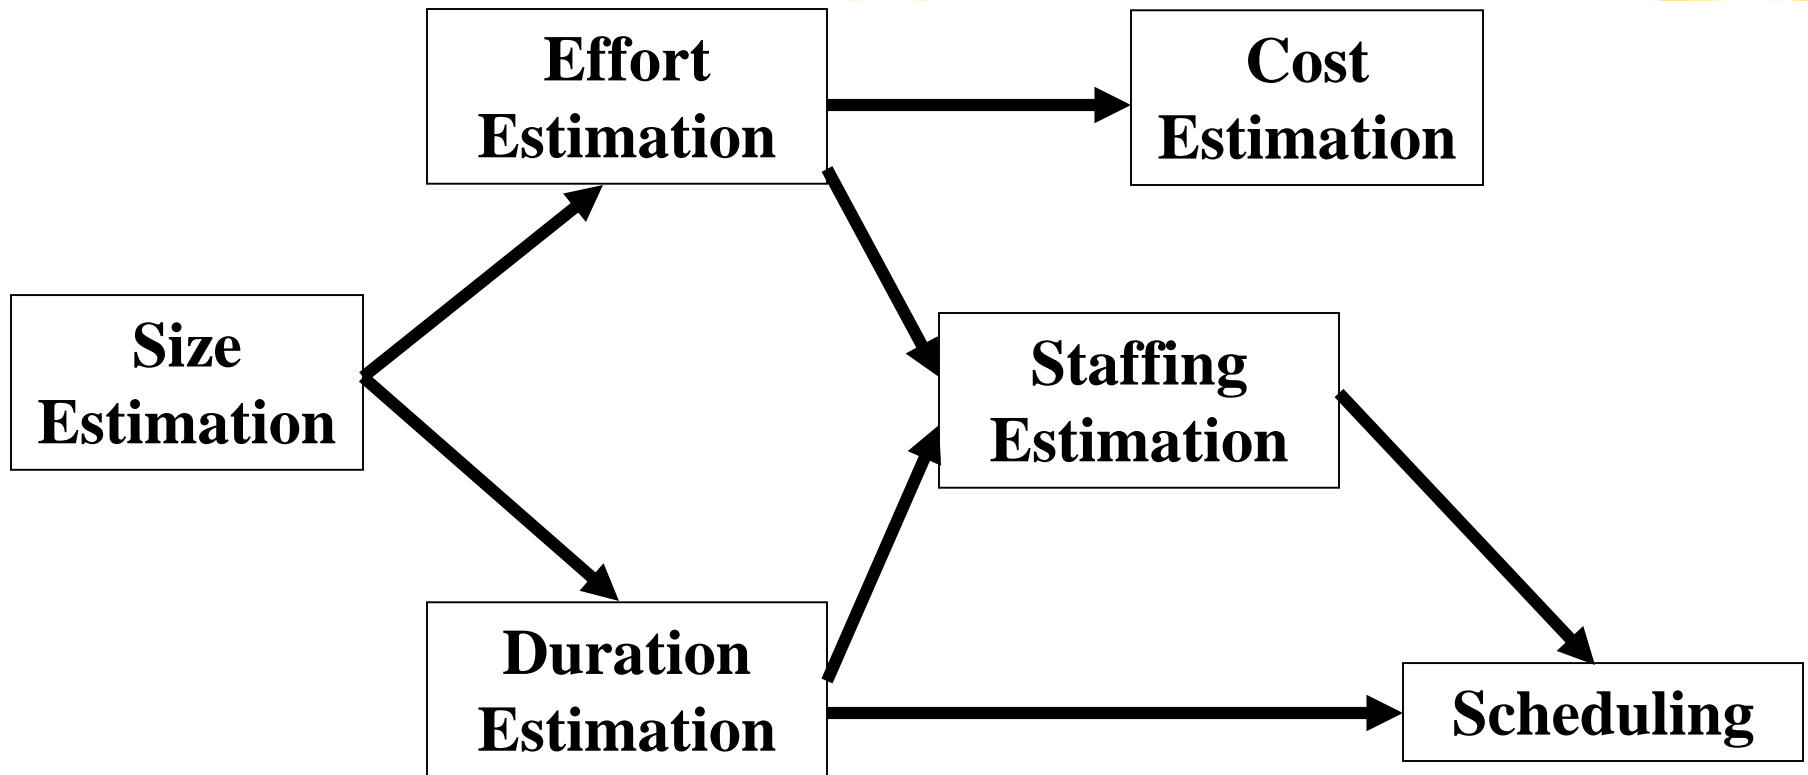

- ☒ **Introduction** (Objectives, Major Functions, Performance Issues, Management and Technical Constraints)
- ☒ **Project Estimates** (Historical Data, Estimation Techniques, Effort, Cost, and Project Duration Estimates)
- ☒ **Project Resources Plan** (People, Hardware and Software, Special Resources)
- ☒ **Schedules** (Work Breakdown Structure, Task Network, Gantt Chart Representation, PERT Chart Representation)
- ☒ **Risk Management Plan** (Risk Analysis, Risk Identification, Risk Estimation, Abatement Procedures)
- ☒ **Project Tracking and Control Plan**
- ☒ **Miscellaneous Plans** (Process Tailoring, Quality Assurance)

# Software Cost Estimation

- ⌘ Determine size of the product.
- ⌘ From the size estimate,
  - ☒ determine the effort needed.
- ⌘ From the effort estimate,
  - ☒ determine project duration, and cost.

# Software Cost Estimation

# Software Cost Estimation

⌘ Three main approaches to estimation:

☑ Empirical

☑ Heuristic

☑ Analytical

# Software Cost Estimation Techniques

## ⌘ Empirical techniques:

- ☒ an educated guess based on past experience.

## ⌘ Heuristic techniques:

- ☒ assume that the characteristics to be estimated can be expressed in terms of some mathematical expression.

## ⌘ Analytical techniques:

- ☒ derive the required results starting from certain simple assumptions.

# Software Size Metrics

## ⌘ LOC (Lines of Code):

- ☑ Simplest and most widely used metric.
- ☑ Comments and blank lines should not be counted.

# Disadvantages of Using LOC

- ⌘ Size can vary with coding style.
- ⌘ Focuses on coding activity alone.
- ⌘ Correlates poorly with quality and efficiency of code.
- ⌘ Penalizes higher level programming languages, code reuse, etc.

# Disadvantages of Using LOC

(cont...)

- ⌘ Measures lexical/textual complexity only.

  - ☐ does not address the issues of structural or logical complexity.

- ⌘ Difficult to estimate LOC from problem description.

  - ☐ So not useful for project planning

# Function Point Metric

⌘ Overcomes some of the shortcomings of the LOC metric

⌘ Proposed by Albrecht in early 80's:

$$\boxed{\wedge} \text{FP} = 4 \quad \# \text{inputs} + 5 \quad \# \text{Outputs} + 4 \\ \# \text{inquiries} + 10 \quad \# \text{files} + 10 \quad \# \text{interfaces}$$

⌘ Input:

⌘ A set of related inputs is counted as one input.

# Function Point Metric

## ⌘ Output:

- ☒ A set of related outputs is counted as one output.

## ⌘ Inquiries:

- ☒ Each user query type is counted.

## ⌘ Files:

- ☒ Files are logically related data and thus can be data structures or physical files.

## ⌘ Interface:

- ☒ Data transfer to other systems.

# Function Point Metric (CONT.)

- ⌘ Suffers from a major drawback:
  - ⌘ the size of a function is considered to be independent of its complexity.
- ⌘ Extend function point metric:
  - ⌘ Feature Point metric:
  - ⌘ considers an extra parameter:
    - ⌘ Algorithm Complexity.

# Function Point Metric (CONT.)

## ⌘ Proponents claim:

- ☑ FP is language independent.
- ☑ Size can be easily derived from problem description

## ⌘ Opponents claim:

- ☑ it is subjective --- Different people can come up with different estimates for the same problem.

# Empirical Size Estimation Techniques

## ⌘ Expert Judgement:

- ☑ An euphemism for guess made by an expert.
- ☑ Suffers from individual bias.

## ⌘ Delphi Estimation:

- ☑ overcomes some of the problems of expert judgement.

# Expert judgement

- ⌘ Experts divide a software product into component units:
  - ☐ e.g. GUI, database module, data communication module, billing module, etc.
- ⌘ Add up the guesses for each of the components.

# Delphi Estimation:

- ⌘ Team of Experts and a coordinator.
- ⌘ Experts carry out estimation independently:
  - ☑ mention the rationale behind their estimation.
  - ☑ coordinator notes down any extraordinary rationale:
    - ☒ circulates among experts.

# Delphi Estimation:

- ⌘ Experts re-estimate.
- ⌘ Experts never meet each other
  - 📁 to discuss their viewpoints.

# Heuristic Estimation Techniques

## ⌘ Single Variable Model:

☒ Parameter to be Estimated =  $C1(\text{Estimated Characteristic})d1$

## ⌘ Multivariable Model:

☒ Assumes that the parameter to be estimated depends on more than one characteristic.

☒ Parameter to be Estimated =  $C1(\text{Estimated Characteristic})d1 + C2(\text{Estimated Characteristic})d2 + \dots$

☒ Usually more accurate than single variable models.

# COCOMO Model

- ⌘ COCOMO (COConstructive COst MOdel) proposed by Boehm.
- ⌘ Divides software product developments into 3 categories:
  - ☑ Organic
  - ☑ Semidetached
  - ☑ Embedded

# COCOMO Product classes

⌘ Roughly correspond to:

- ⏏ application, utility and system programs respectively.
  - ⊗ Data processing and scientific programs are considered to be **application programs**.
  - ⊗ Compilers, linkers, editors, etc., are **utility programs**.
  - ⊗ Operating systems and real-time system programs, etc. are **system programs**.

# Elaboration of Product classes

## ⌘ Organic:

- ⌘ Relatively small groups
  - ⌘ working to develop well-understood applications.

## ⌘ Semidetached:

- ⌘ Project team consists of a mixture of experienced and inexperienced staff.

## ⌘ Embedded:

- ⌘ The software is strongly coupled to complex hardware, or real-time systems.

# COCOMO Model (CONT.)

⌘ For each of the three product categories:

- ☒ From size estimation (in KLOC), Boehm provides equations to predict:

- ☒ project duration in months

- ☒ effort in programmer-months

⌘ Boehm obtained these equations:

- ☒ examined historical data collected from a large number of actual projects.

# COCOMO Model (CONT.)

⌘ Software cost estimation is done through three stages:

- ☑ Basic COCOMO,
- ☑ Intermediate COCOMO,
- ☑ Complete COCOMO.

# Basic COCOMO Model (CONT.)

⌘ Gives only an approximate estimation:

$$\boxed{\wedge} \text{Effort} = a1 \text{ (KLOC)} a2$$

$$\boxed{\wedge} T_{dev} = b1 \text{ (Effort)} b2$$

⊗ KLOC is the estimated kilo lines of source code,

⊗  $a1, a2, b1, b2$  are constants for different categories of software products,

⊗  $T_{dev}$  is the estimated time to develop the software in months,

⊗ Effort estimation is obtained in terms of person months (PMs)

# Development Effort Estimation

⌘ Organic :

$$\boxed{\wedge} \text{ Effort} = 2.4 (\text{KLOC})^{1.05} \text{ PM}$$

⌘ Semi-detached:

$$\boxed{\wedge} \text{ Effort} = 3.0 (\text{KLOC})^{1.12} \text{ PM}$$

⌘ Embedded:

$$\boxed{\wedge} \text{ Effort} = 3.6 (\text{KLOC})^{1.20} \text{ PM}$$

# Development Time Estimation

⌘ Organic:

$$\boxed{\wedge} T_{dev} = 2.5 (\text{Effort})^{0.38} \text{ Months}$$

⌘ Semi-detached:

$$\boxed{\wedge} T_{dev} = 2.5 (\text{Effort})^{0.35} \text{ Months}$$

⌘ Embedded:

$$\boxed{\wedge} T_{dev} = 2.5 (\text{Effort})^{0.32} \text{ Months}$$

# Basic COCOMO Model (CONT.)

⌘ Effort is somewhat super-linear in problem size.

# Basic COCOMO Model (CONT.)

## ⌘ Development time

☐ sublinear function of product size.

## ⌘ When product size increases two times,

☐ development time does not double.

## ⌘ Time taken:

☐ almost same for all the three product categories.

# Basic COCOMO Model (CONT.)

- ⌘ Development time does not increase linearly with product size:
  - ⏏ For larger products more parallel activities can be identified:
    - ⏏ can be carried out simultaneously by a number of engineers.

# Basic COCOMO Model (CONT.)

⌘ Development time is roughly the same for all the three categories of products:

- ☑ For example, a 60 KLOC program can be developed in approximately 18 months

- ☒ regardless of whether it is of organic, semi-detached, or embedded type.

- ☑ There is more scope for parallel activities for system and application programs,

- ☒ than utility programs.

# Example

⌘ The size of an organic software product has been estimated to be 32,000 lines of source code.

---

⌘  $\text{Effort} = 2.4 * (32)^{1.05} = 91 \text{ PM}$

⌘  $\text{Nominal development time} = 2.5 * (91)^{0.38} = 14 \text{ months}$

# Intermediate COCOMO

⌘ Basic COCOMO model assumes

☑ effort and development time depend on product size alone.

⌘ However, several parameters affect effort and development time:

☒ Reliability requirements

☒ Availability of CASE tools and modern facilities to the developers

☒ Size of data to be handled

# Intermediate COCOMO

⌘ For accurate estimation,

- ☑ the effect of all relevant parameters must be considered:

- ☑ **Intermediate COCOMO model** recognizes this fact:

- ☒ refines the initial estimate obtained by the basic COCOMO by using a set of 15 cost drivers (multipliers).

# Intermediate COCOMO

(CONT.)

⌘ If modern programming practices are used,

⏏ initial estimates are scaled downwards.

⌘ If there are stringent reliability requirements on the product :

⏏ initial estimate is scaled upwards.

# Intermediate COCOMO

(CONT.)

⌘ Rate different parameters on a scale of one to three:

- ☒ Depending on these ratings,
- ☒ multiply cost driver values with the estimate obtained using the basic COCOMO.

# Intermediate COCOMO

(CONT.)

## ⌘ Cost driver classes:

- ☒ Product: Inherent complexity of the product, reliability requirements of the product, etc.
- ☒ Computer: Execution time, storage requirements, etc.
- ☒ Personnel: Experience of personnel, etc.
- ☒ Development Environment: Sophistication of the tools used for software development.

# Shortcoming of basic and intermediate COCOMO models

⌘ Both models:

- ☒ consider a software product as a single homogeneous entity:
- ☒ However, most large systems are made up of several smaller sub-systems.
  - ☒ Some sub-systems may be considered as organic type, some may be considered embedded, etc.
  - ☒ for some the reliability requirements may be high, and so on.

# Complete COCOMO

- ⌘ Cost of each sub-system is estimated separately.
- ⌘ Costs of the sub-systems are added to obtain total cost.
- ⌘ Reduces the margin of error in the final estimate.

# Complete COCOMO

## Example

- ⌘ A Management Information System (MIS) for an organization having offices at several places across the country:
  - ☒ Database part (semi-detached)
  - ☒ Graphical User Interface (GUI) part (organic)
  - ☒ Communication part (embedded)
- ⌘ Costs of the components are estimated separately:
  - ☒ summed up to give the overall cost of the system.

# Halstead's Software Science

⌘ An analytical technique to estimate:

☐ size,

☐ development effort,

☐ development time.

# Halstead's Software Science

⌘ Halstead used a few primitive program parameters

- ⌘ number of operators and operands

⌘ Derived expressions for:

- ⌘ over all program length,
- ⌘ potential minimum volume
- ⌘ actual volume,
- ⌘ language level,
- ⌘ effort, and
- ⌘ development time.

# Staffing Level Estimation

- ⌘ Number of personnel required during any development project:
  - ☒ not constant.
- ⌘ Norden in 1958 analyzed many R&D projects, and observed:
  - ☒ Rayleigh curve represents the number of full-time personnel required at any time.

# Rayleigh Curve

⌘ Rayleigh curve is specified by two parameters:

⌘  $t_d$  the time at which the curve reaches its maximum

⌘  $K$  the total area under the curve.

⌘  $L = f(K, t_d)$

# Putnam's Work:

⌘ In 1976, Putnam studied the problem of staffing of software projects:

- ☐ observed that the level of effort required in software development efforts has a similar envelope.

- ☐ found that the Rayleigh-Norden curve

  - ☒ relates the number of delivered lines of code to effort and development time.

# Putnam's Work (CONT.)

⌘ Putnam analyzed a large number of army projects, and derived the expression:

$$L = C_k K^{1/3} t_d^{4/3}$$

☐ K is the effort expended and L is the size in KLOC.

☐  $t_d$  is the time to develop the software.

☐  $C_k$  is the state of technology constant

☒ reflects factors that affect programmer productivity.

# Putnam's Work (CONT.)

- ⌘  $C_k=2$  for poor development environment
  - ☒ no methodology, poor documentation, and review, etc.
- ⌘  $C_k=8$  for good software development environment
  - ☒ software engineering principles used
- ⌘  $C_k=11$  for an excellent environment

# Rayleigh Curve

- ⌘ Very small number of engineers are needed at the beginning of a project
  - ☐ carry out planning and specification.
- ⌘ As the project progresses:
  - ☐ more detailed work is required,
  - ☐ number of engineers slowly increases and reaches a peak.

# Rayleigh Curve

⌘ Putnam observed that:

- ☒ the time at which the Rayleigh curve reaches its maximum value

- ☒ corresponds to system testing and product release.

- ☒ After system testing,

- ☒ the number of project staff falls till product installation and delivery.

# Rayleigh Curve

⌘ From the Rayleigh curve observe that:

☐ approximately 40% of the area under the Rayleigh curve is to the left of  $t_d$

☐ and 60% to the right.

# Effect of Schedule Change on Cost

⌘ Using the Putnam's expression for L,

$$K = L^3 / Ck^3 td^4$$

$$\text{Or, } K = C_1 / td^4$$

⌘ For the same product size,

$C_1 = L^3 / Ck^3$  is a constant.

⌘ Or,  $K_1 / K_2 = td_2^4 / td_1^4$

# Effect of Schedule Change on Cost (CONT.)

## ⌘ Observe:

- ☐ a relatively small compression in delivery schedule
  - ☒ can result in substantial penalty on human effort.

## ⌘ Also, observe:

- ☐ benefits can be gained by using fewer people over a somewhat longer time span.

# Example

⌘ If the estimated development time is 1 year, then in order to develop the product in 6 months,

⏏ the total effort and hence the cost increases 16 times.

⏏ In other words,

⏏ the relationship between effort and the chronological delivery time is highly nonlinear.

# Effect of Schedule Change on Cost (CONT.)

- ⌘ Putnam model indicates extreme penalty for schedule compression
  - ⏏ and extreme reward for expanding the schedule.
- ⌘ Putnam estimation model works reasonably well for very large systems,
  - ⏏ but seriously overestimates the effort for medium and small systems.

# Effect of Schedule Change on Cost (CONT.)

⌘ Boehm observed:

☐ "There is a limit beyond which the schedule of a software project cannot be reduced by buying any more personnel or equipment."

☐ This limit occurs roughly at 75% of the nominal time estimate.

# Effect of Schedule Change on Cost (CONT.)

⌘ If a project manager accepts a customer demand to compress the development time by more than 25%

⏏ very unlikely to succeed.

- ⊗ every project has only a limited amount of parallel activities
- ⊗ sequential activities cannot be speeded up by hiring any number of additional engineers.
- ⊗ many engineers have to sit idle.

# Jensen Model

⌘ Jensen model is very similar to Putnam model.

- ☑ attempts to soften the effect of schedule compression on effort

- ☑ makes it applicable to smaller and medium sized projects.

# Jensen Model

⌘ Jensen proposed the equation:

☒  $L = C_{te} t_d K^{1/2}$

☒ Where,

☒  $C_{te}$  is the effective technology constant,

☒  $t_d$  is the time to develop the software, and

☒  $K$  is the effort needed to develop the software.

# Organization Structure

## ⌘ Functional Organization:

- ☑ Engineers are organized into functional groups, e.g.
  - ☒ specification, design, coding, testing, maintenance, etc.
- ☑ Engineers from functional groups get assigned to different projects

# Advantages of Functional Organization

- ⌘ Specialization
- ⌘ Ease of staffing
- ⌘ Good documentation is produced
  - ☑ different phases are carried out by different teams of engineers.
- ⌘ Helps identify errors earlier.

# Project Organization

- ⌘ Engineers get assigned to a project for the entire duration of the project
  - ☑ Same set of engineers carry out all the phases
- ⌘ Advantages:
  - ☑ Engineers save time on learning details of every project.
  - ☑ Leads to job rotation

# Team Structure

⌘ Problems of different complexities and sizes require different team structures:

- ☑ Chief-programmer team

- ☑ Democratic team

- ☑ Mixed organization

# Democratic Teams

⌘ Suitable for:

- ☐ small projects requiring less than five or six engineers
- ☐ research-oriented projects

⌘ A manager provides administrative leadership:

- ☐ at different times different members of the group provide technical leadership.

# Democratic Teams

- ⌘ Democratic organization provides
  - ☑ higher morale and job satisfaction to the engineers
  - ☑ therefore leads to less employee turnover.
- ⌘ Suitable for less understood problems,
  - ☑ a group of engineers can invent better solutions than a single individual.

# Democratic Teams

## ⌘ Disadvantage:

⏏ team members may waste a lot time arguing about trivial points:

⏏ absence of any authority in the team.

# Chief Programmer Team

⌘ A senior engineer provides technical leadership:

- ☑ partitions the task among the team members.
- ☑ verifies and integrates the products developed by the members.

# Chief Programmer Team

⌘ Works well when

- ☑ the task is well understood

  - ☑ also within the intellectual grasp of a single individual,

- ☑ importance of early completion outweighs other factors

  - ☑ team morale, personal development, etc.

# Chief Programmer Team

⌘ Chief programmer team is subject to single point failure:

☐ too much responsibility and authority is assigned to the chief programmer.

# Mixed Control Team Organization

- ⌘ Draws upon ideas from both:
  - ☐ democratic organization and
  - ☐ chief-programmer team organization.
- ⌘ Communication is limited
  - ☐ to a small group that is most likely to benefit from it.
- ⌘ Suitable for large organizations.

# Team Organization

# Mixed team organization

# Summary

⌘ We discussed the broad responsibilities of the project manager:

- ☐ Project planning

- ☐ Project Monitoring and Control

# Summary

⌘ To estimate software cost:

- ☑ Determine size of the product.

- ☑ Using size estimate,
  - ☒ determine effort needed.

- ☑ From the effort estimate,
  - ☒ determine project duration, and cost.

# Summary (CONT.)

## ⌘ Cost estimation techniques:

- ☑ Empirical Techniques
- ☑ Heuristic Techniques
- ☑ Analytical Techniques

## ⌘ Empirical techniques:

- ☑ based on systematic guesses by experts.
  - ☒ Expert Judgement
  - ☒ Delphi Estimation

# Summary (CONT.)

## ⌘ Heuristic techniques:

- ☑ assume that characteristics of a software product can be modeled by a mathematical expression.
- ☑ COCOMO

## ⌘ Analytical techniques:

- ☑ **derive** the estimates starting with some basic assumptions:
- ☑ Halstead's Software Science

# Summary (CONT.)

- ⌘ The staffing level during the life cycle of a software product development:
  - ☐ follows Rayleigh curve
  - ☐ maximum number of engineers required during testing.

# Summary (CONT.)

- ⌘ Relationship between schedule change and effort:
  - ☐ highly nonlinear.
- ⌘ Software organizations are usually organized in:
  - ☐ functional format
  - ☐ project format

# Summary (CONT.)

⌘ Project teams can be organized in following ways:

- ☑ Chief programmer: suitable for routine work.
- ☑ Democratic: Small teams doing R&D type work
- ☑ Mixed: Large projects
